Biology

Assessment Unit A2 2

assessing

Biochemistry, Genetics and Evolutionary Trends

[AB221]
MONDAY 1 JUNE, AFTERNOON

TIME
2 hours.

INSTRUCTIONS TO CANDIDATES
Write your Centre Number and Candidate Number in the spaces provided at the top of this page.
Write your answers in the spaces provided in this question paper.
There is an extra lined page at the end of the paper if required.
Answer all eight questions.

INFORMATION FOR CANDIDATES
The total mark for this paper is 90.
Section A carries 72 marks. Section B carries 18 marks.
Figures in brackets printed down the right-hand side of pages indicate the marks awarded to each question or part question.
You are reminded of the need for good English and clear presentation in your answers.
Use accurate scientific terminology in all answers.
You should spend approximately 25 minutes on Section B.
You are expected to answer Section B in continuous prose.
Quality of written communication will be assessed in Section B, and awarded a maximum of 2 marks.
Statistics sheets are provided for use with this paper.
An understanding of the structure of DNA has led to the development of gene technology. One application of gene technology is the production of transgenic organisms.

(a) Explain precisely the term ‘transgenic organism’.

________________________________________________________________________
________________________________________________________________________
________________________________________________________________________ [1]

(b) Molecules, such as human growth hormone, can be produced via genetic engineering.

Describe the role of the following in genetic engineering:

• reverse transcriptase

________________________________________________________________________
________________________________________________________________________
________________________________________________________________________

• DNA polymerase

________________________________________________________________________
________________________________________________________________________
________________________________________________________________________

• plasmids

________________________________________________________________________
________________________________________________________________________
________________________________________________________________________ [3]
2 (a) Insulin is a hormone involved in the regulation of blood glucose. It is produced in specialised cells in the pancreas and consists of two polypeptide chains (A and B) made up of 51 amino acids in total.

Following the formation of an initial ‘precursor’ molecule, proinsulin, a linking sequence of amino acids is removed to leave the two separate chains which form insulin.

This is summarised in the diagram below.

Using the information provided:

(i) Identify process X.

X ________________________________ [1]

(ii) State the evidence which indicates that only one gene codes for insulin.

______________________________________________________________
______________________________________________________________
______________________________________________________________
______________________________________________________________ [1]
(b) Ribosomes are small organelles involved in protein synthesis.

(i) Describe concisely the role of ribosomes in protein synthesis.

(ii) Many ribosomes often work on the same individual strand of mRNA, in localised ‘hot spots’ of protein synthesis. In this way, large quantities of a particular polypeptide can be made. Suggest two advantages of this.

1. 
2. 

[2]
3 Photosynthesis involves a number of different plant pigments which absorb light energy.

(a) Describe one advantage of plants having different pigments to absorb light energy.

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________ [1]

(b) In deciduous trees the leaves emerge in spring and are lost in autumn. Suggest one advantage to trees of losing their leaves in autumn.

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________ [1]

(c) Chromatography can be used to separate and identify the photosynthetic pigments present in a leaf. In an investigation, chromatography was used to compare and contrast the photosynthetic pigments present in the leaves of a particular species. This was done in May (at the start of the growing season) and in October (at the end of the growing season).

The results of the investigation are shown in the table below. Assume the technique used to extract the pigments was equally effective in both May and October.

<table>
<thead>
<tr>
<th>Pigment</th>
<th>Colour of pigment</th>
<th>Intensity of colour</th>
<th>Colour of pigment</th>
<th>Intensity of colour</th>
</tr>
</thead>
<tbody>
<tr>

(i) Using the information provided, explain why the leaves of this species would be coloured green in May but would appear yellow-brown in October.

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________ [3]

(ii) In this investigation it is important to control as many variables as possible. Suggest one variable that should be controlled and explain the reason for controlling it.

Variable ______________________________________________________________

Reason _________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________ [2]
(d) The light-dependent reaction of photosynthesis is summarised in the diagram below. However, the process of photolysis is not included.

(i) Using the diagram and your knowledge, describe what happens to the products of photolysis (the splitting of water) in the above reaction.

________________________________________________________________________
________________________________________________________________________
________________________________________________________________________

__________________________________________________________________________

__________________________________________________________________________

__________________________________________________________________________

__________________________________________________________________________ [2]
Sickle cell anaemia is a condition caused by a mutation in a gene that codes for haemoglobin. In a mutated gene, the normal DNA sequence of the base triplet CTC is changed to CAC.

(a) (i) Name the type of mutation involved.

_____________________________ [1]

(ii) State the change in the affected mRNA codon.

___________ to ___________ [1]

The table below shows the ‘genetic dictionary’ indicating the amino acids coded for by mRNA codons.

</tbody>
</table>
(iii) Using the information in the table:

- State the change in the amino acid coded for as a consequence of the sickle cell anaemia mutation.

_____________ to ____________ [1]

- Explain precisely what is meant by the ‘degenerate nature of the genetic code’.

________________________________________________

________________________________________________

________________________________________________

________________________________________________

________________________________________________

________________________________________________ [2]

Sickle cell anaemia results in red blood cells becoming more rigid. Many red blood cells in individuals with sickle cell anaemia are therefore less flexible than those in unaffected individuals.

(b) Suggest the effect that sickle cell anaemia has on blood flow in the capillaries of an affected individual.

_______________________________________________________

_____________________________________________________

_____________________________________________________

[1]
People with two copies of the mutated allele have sickle cell anaemia. These individuals have very restricted oxygen-carrying capacity and have reduced life expectancy.

People with one normal allele and one mutated allele (i.e. heterozygotes) are said to have sickle cell trait. These heterozygotes have less efficient oxygen-carrying capacity but can carry out activities that do not require high energy levels.

Evidence shows that heterozygotes have some protection against malaria. Malaria is a disease caused by a parasite which carries out part of its life cycle within the red blood cells. The red blood cells in individuals carrying at least one sickle cell allele are not easily penetrated by the parasite. The parasite is transmitted from person to person by mosquito bites. Mosquitoes are particularly common in hot climates, such as much of central Africa, but are unable to live in colder climates.

(c) Explain why the frequency of the sickle cell allele remains at high levels in parts of Africa yet is very low in northern Europe.

__________________________________________________________________________

__________________________________________________________________________

__________________________________________________________________________

__________________________________________________________________________  [5]
Ash ‘dieback’ is a fungal disease which has caused the destruction of many ash (*Fraxinus excelsior*) woodlands in Europe, including well over half of the ash trees in Denmark.

In March 2012, the first case of this infection in Britain was reported. By 2013, the disease had spread across native woodlands in south east England and was also found in other isolated pockets in England, Scotland and Wales.

It is thought that the fungus responsible, *Chalara fraxinea*, was carried to Britain from mainland Europe in infected seedlings and young trees. Once in Britain the infection spread rapidly from tree to tree by wind-borne spores, with a typical dispersal range of up to ten miles.

In early 2013, the only examples of infected ash trees in Northern Ireland were in sites which had been recently planted with commercially grown seedlings. There were no reported cases in native woodland.

(a) Suggest why the first cases of *Chalara fraxinea* infection in Northern Ireland were in new plantations, but not in native woodland.

_______________________________________________________
_______________________________________________________
_______________________________________________________
_______________________________________________________
_______________________________________________________
_______________________________________________________
_______________________________________________________ [2]
(b) Several strategies are being used to control the spread of the disease. One strategy involves developing an understanding of the genome of the ash. In 2013 its genome was sequenced for the first time.

(i) Explain fully the term ‘genome sequencing’.

(ii) A strain of ash (referred to as ‘tree-35’) resistant to the fungus has been identified in Denmark. This strain originated around 100 years ago and currently makes up two percent of Danish ash trees.

Suggest how knowledge of the genomes of both the native British ash and ‘tree-35’ could be used to help conserve native British ash woodland.

[2]

[3]
(c) The human genome has also been sequenced. As a result, it is now possible to test an individual for the presence of alleles that increase susceptibility to certain medical conditions, such as some cancers and heart disease.

(i) There has been limited progress in directly linking alleles to conditions such as cancer and heart disease. Suggest two reasons for this limited progress.

1. ___________________________________________________
   ___________________________________________________
   ___________________________________________________

2. ___________________________________________________
   ___________________________________________________
   ___________________________________________________

(ii) In terms of treatment, continued research into the link between alleles and disease is likely to be beneficial.

In this context, explain the term ‘designer drug’ and suggest one advantage of developing such drugs.

___________________________________________________
___________________________________________________
___________________________________________________
___________________________________________________
___________________________________________________
___________________________________________________ [2]
6 (a) The structure of an ATP molecule is represented in the diagram below.

(i) Identify the part of the molecule labelled X in the diagram.

X _______________________________ [1]

(ii) Explain what happens when an ATP molecule is hydrolysed to ADP.

_________________________________________________________________________
_________________________________________________________________________
_________________________________________________________________________ [1]

(iii) Give two advantages of using ATP as an immediate energy source within the cell, rather than glucose.

1. _______________________________________________________________________
________________________________________________________________________

2. _______________________________________________________________________
________________________________________________________________________ [2]
(b) It was noticed that one variety of a pea species (A) had a more rapid growth rate than another variety (B). It was suggested that this was due to variety A having a faster respiration rate.

In an investigation to compare respiration rates in the two varieties, two sets of the apparatus shown in the diagram below were used. (This apparatus is similar in principle to a standard respirometer.)

For each variety, 10 g of soaked peas were placed in the glass container with an airtight bung. The level of potassium hydroxide was adjusted to 100 cm$^3$ on the scale by raising or lowering the levelling arm.

Both sets of apparatus were placed in a dark cupboard for 12 hours. The readings on the scales were recorded every two hours.

(i) Explain why the investigation was conducted in darkness.

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________

________________________________________________________________________ [2]
The results of the investigation are shown in the graph below.

(ii) Suggest an explanation for the faster rate of oxygen uptake in variety B between 0–2 hours.

____________________________________________________________________________________

____________________________________________________________________________________

____________________________________________________________________________________ [1]

(iii) Calculate the mean rate of respiration of variety A between 2 and 12 hours in cm$^3$ of oxygen used per gram of pea seed per hour. (Show your working.)

________________________ cm$^3$ oxygen g$^{-1}$ hr$^{-1}$ [3]
(c) It was suggested that the overall faster respiration rate in variety A was due to there being more mitochondria in the cells of variety A than in those of variety B. Thin sections of pea tissue were prepared from each variety and mitochondria in 100 cells of each variety were counted.

The results are shown in the following table.

<table>
<thead>
<tr>
<th>Variety of pea</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>Number of cells in section (n)</td>
<td>100</td>
<td>100</td>
</tr>
<tr>
<td>Mean number of mitochondria in each cell ((\bar{x}))</td>
<td>6.3</td>
<td>5.8</td>
</tr>
<tr>
<td>Standard deviation (error) of the mean ((\hat{\sigma}))</td>
<td>0.62</td>
<td>0.68</td>
</tr>
</tbody>
</table>

The \(t\)-test can be used to compare the number of mitochondria in the two varieties.

(i) State the null hypothesis for this test.

______________________________________________________________________

______________________________________________________________________

______________________________________________________________________ [1]

(ii) Calculate the value of \(t\) using data from the table above.
(Show your working.)

Answer_________________________ [2]
(iii) State the probability value for the calculated $t$.

_________________________________________________ [1]

(iv) State your decision regarding the null hypothesis and comment on this outcome.

_________________________________________________

_________________________________________________

_________________________________________________

_________________________________________________

_________________________________________________ [2]
The fruit fly, *Drosophila melanogaster*, is ideally suited for genetic investigations and has been widely used for this purpose for many years.

The normal eye colour in *Drosophila* is red but a white-eyed form exists. In the genetics of eye colour, red eye (R) is dominant to white eye (r) and the inheritance of eye colour is sex linked (in a similar way to sex linked conditions in humans).

(a) State the genotypes of:

- a male with red eyes
  
  ________________________________

- a female with white eyes
  
  ________________________________ [2]

(b) In a particular cross, a red-eyed female was crossed with a red-eyed male. The offspring produced are shown in the following table.

<table>
<thead>
<tr>
<th></th>
<th>Red eyes</th>
<th>White eyes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Males</strong></td>
<td>48</td>
<td>53</td>
</tr>
<tr>
<td><strong>Females</strong></td>
<td>102</td>
<td>0</td>
</tr>
</tbody>
</table>

(i) Using a genetic diagram, explain the outcome of this cross.
(ii) As with most genetic crosses, the numbers of offspring in this cross do not fit exactly with the predicted ratio. State the name of the statistical test that can be used to identify if observed offspring numbers are significantly different from expected numbers.

_____________________________ [1]

(c) In *Drosophila*, the genes for wing type and body colour are located on separate autosomes and so are independently inherited. Normal wing is dominant to vestigial wing and normal body colour is dominant to ebony body colour.

A cross between a fruit fly with normal wings and normal body colour and one with vestigial wings and ebony body colour produced offspring displaying four different phenotypes.

Using a genetic diagram, explain these results.
(Let $A =$ normal wing and $B =$ normal body colour)

(d) Suggest two reasons why *Drosophila melanogaster* is ideally suited for genetic investigations.

1. ____________________________

2. ____________________________ [2]
Section B

Quality of written communication is awarded a maximum of 2 marks in this section.

8 The divisions in the plant kingdom and the phyla in the animal kingdom show progression in levels of organisation across the major groups.

(a) In the plant kingdom, one aspect of this progression involves an increasing ability to survive in drier environments. Describe and explain the levels of progression, in terms of this ability, across the major plant groups (i.e. the mosses, ferns and angiosperms). [10]

(b) In the animal kingdom, the phyla show increasing complexity in the sequence Cnidaria, Platyhelminthes, Annelida and Chordata. Describe and explain how evolutionary progression is evident in this sequence. [6]

Quality of written communication [2]

(a) In the plant kingdom, one aspect of this progression involves an increasing ability to survive in drier environments. Describe and explain the levels of progression, in terms of this ability, across the major plant groups (i.e. the mosses, ferns and angiosperms).
